

## Q3 Short Video Classification

To train a classifier from scratch for a video classification problem is very time consuming and also very computationally intensive. Therefore, I used a pretrained 3d Swin-Transformer and fine-tuned on our dataset with a 3-layer mlp protocol.

3d swin transformer efficiently extracts video features in both temporal and spatial dimensions and with a 3-layer linear protocol, we can use the features extracted by 3d swin transformer and deal with the classification problem.

### Data Preprocessing

Thanks to the Github repo

<https://github.com/YuxinZhaozyx/pytorch-VideoDataset/tree/master>, with the help of this great repository, I can easily process the video format data and convert them into Pytorch Tensor which allows the 3d swin-transformer to be trained. Also, I do some data augmentation to enhance the robustness of our model.

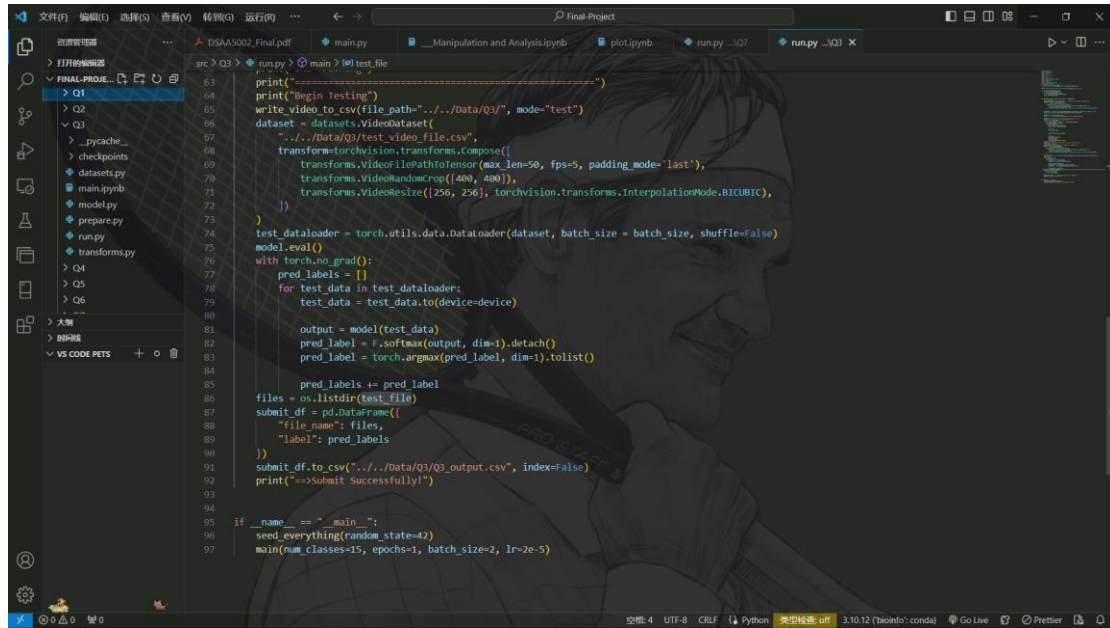

### Fine-tuning

The 3d swin-transformer 3d can be regarded as a feature extractor, we use those features extracted by well pretrained model to perform on the downstream tasks. In this case, I design a 3-layer MLP to do the classification problem on our datasets.

After around 1 hour fine-tuning, I do the inference and get the predict labels on test dataset.

### Experiment Screenshot

Here is the screenshot of this Q3 task, I done this task on the cloud platform with a piece of V100 GPU.

```
[1]: from run import seed_everything, main
```

```
[2]: seed_everything(random_state=42)
main(num_classes=15, epochs=1, batch_size=2, lr=2e-5, test_file="../../Data/Q3/test_video/")
```

```
Begin Fine-tuning on Our weather dataset
